

My Net Zero APP – Core Summary

Comparing Conventional Frameworks with Earth System Accounting

"Today's Net Zero primarily asks how much less humans can emit. This research asks the missing question: how much more can Earth absorb if we stop destroying its natural capacity to do so?"

1. Framework Comparison & Formulas

Conventional Net Zero

Focuses on anthropogenic emissions & artificial removals.

$$\text{Human Emissions} - \text{Anthropogenic Reduction/Removal} = 0$$

This Research (Earth System View)

Includes lost natural sink capacities (forests, soil, oceans).

$$\text{Emissions} - \text{Nature's CO}_2 \text{ Removal} = 0$$

2. Climate Burden Attribution (30-Year Empirical Data)

Based on the research model's baseline global annual GHG emission framework of ~50 GtCO₂eq:

Sector / Burden Source	Conventional Attribution	This Research (Earth System Accounting)
Livestock-related Activities (Energy, methane, land-use change & lost natural sink capacity)	Minor direct emissions (~14.5%)	166% (relative to the ~50 GtCO ₂ eq baseline)*
Fossil-fuel-related Emissions	Dominant source (~70-80%)	46% (relative to the ~50 GtCO ₂ eq baseline)

* Livestock-related 166% excludes ocean impacts by livestock.

3. Policy Mechanism & Empirical Model Findings

Core Intervention Path:

Reduce livestock pressure -> Restore natural systems -> Increase natural CO₂ removal

Empirical Model Outcome (Dietary Transition):

Baseline Reference: Calibrated against the global ~50 GtCO₂eq emissions
